Lab 9: Hierarchical GLM

Toufic Ayoub

17/03/23

Lip cancer data

- aff.i is proportion of male population working outside in each region
- observe.i is observed deaths in each region
- expect.i is expected deaths, based on region-specific age distribution and national-level age-specific mortality rates.

```

Question 1

• Explain a bit more what the expect.i variable is. For example, if a particular area has an expected deaths of 6, what does this mean?

Expected deaths is the implied number of lip cancer deaths for a particular region given that region's age structure and the national level age-specific mortality rates for lip cancer. For example, an expected number of deaths of 6 would mean for that particular region, we would expect 6 lip cancer deaths if this region were to experience the same age specific mortality rates as at the national level.

Question 2

- Run three different models in Stan with three different set-up's for estimating θ_i , that is the relative risk of lip cancer in each region:
- 1. Intercept α_i is same in each region = α
- 2. α_i is different in each region and modeled separately (with covariate)
- 3. α_i is different in each region and the intercept is modeled hierarchically (with covariate)

We have:

$$y_i | \theta_i \sim \text{Poisson}(\theta_i \cdot e_i)$$

We want to look at three models for $\log(\theta_i)$.

Model 1:

 $\log(\theta_i) = \alpha + \beta x_i$

Model 2:

 $\log(\theta_i) = \alpha_i + \beta x_i$

Model 3:

 $\log(\theta_i) = \alpha_i + \beta x_i$

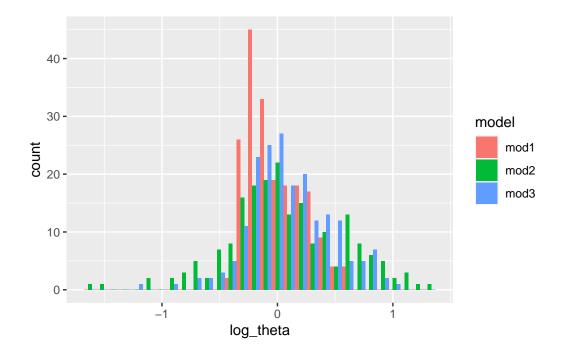

with

$$\alpha_i \sim N(\mu, \sigma^2)$$

Question 3

• Make two plots (appropriately labeled and described) that illustrate the differences in estimated θ_i 's across regions and the differences in θ s across models.

```
res_mod1 = mod1 |>
  gather_draws(log_theta[i]) |>
  median_qi() |>
  rename(median_mod1 = .value,
         lower_mod1 = .lower,
         upper_mod1 = .upper) |>
  select(i, median_mod1:upper_mod1)
res_mod2 = mod2 |>
  gather_draws(log_theta[i]) |>
  median_qi() |>
  rename(median_mod2 = .value,
         lower_mod2 = .lower,
         upper_mod2 = .upper) |>
  select(i, median_mod2:upper_mod2)
res_mod3 = mod3 |>
  gather_draws(log_theta[i]) |>
  median_qi() |>
  rename(median_mod3 = .value,
         lower_mod3 = .lower,
         upper_mod3 = .upper) |>
  select(i, median_mod3:upper_mod3)
res = res_mod1 |>
  left_join(res_mod2) |>
  left_join(res_mod3)
res|>
  select(median_mod1,median_mod2,median_mod3) |>
  pivot_longer(median_mod1:median_mod3, names_to = "model",
               values_to = "log_theta") |>
  mutate(model = str_remove(model, "median_")) |>
  ggplot(aes(log_theta, fill = model)) +
  geom_histogram(position = "dodge")
```

```
res |>
mutate(deaths = observe.i) |>
mutate(log_smr = log(observe.i/expect.i)) |>
ggplot(aes(log_smr, median_mod1, color = "Model 1")) +
    geom_point(aes(size = deaths), alpha = 0.6) +
    geom_errorbar(aes(ymin = lower_mod1, ymax = upper_mod1, color = "Model 1")) +
    geom_abline(slope = 1, intercept = 0) +
    geom_point(aes(log_smr, median_mod2, color = "Model 2"), alpha = 0.6) +
    geom_errorbar(aes(ymin = lower_mod2, ymax = upper_mod2, color = "Model 2"),
        alpha = 0.6) +
    geom_point(aes(log_smr, median_mod3, color = "Model 3"), alpha = 0.6) +
    geom_errorbar(aes(ymin = lower_mod3, ymax = upper_mod3, color = "Model 3"),
        alpha = 0.6)
```
